## 1 Model

The d dimensional torus  $\mathbb{T}^d$  can be defined as  $(\mathbb{R}/n\mathbb{Z})^d$  for some natural n. And we can represent this as a cell-complex with cubical d-dimensional cells  $(\mathbb{Z}/n\mathbb{Z})^d + [0,1]^d$  and all their k-faces for k = 0, ..., d.

We randomly assume the filtration value for each k-face uniformly distributed in [k, k+1]. This filtration on segmented torus will corespond some real filtration  $f\mathbb{T}^d \to \mathbb{R}$ , s.t. the d-dimensional cells will corespond the local maximums, vertices will corespond the local minimums and other k-faces will be saddles.

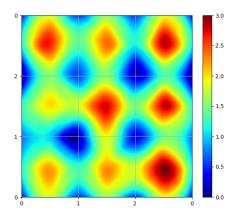

Figure 1: The example of the filtration  $f: \mathbb{T}^2 \to \mathbb{R}$ , s.t. there are local minimums in the vertices, saddles in the middle of edges, and the local maximums in the centers of square cells.

## 2 Scores

#### 2.1 Poset Scores

- number\_of\_nodes : Returns the number of nodes in the poset.
- **number\_of\_relations** : Returns the number of relations in the transitive reduction.
- number\_of\_components : Returns the number of connected components in the poset
- cycles\_dimension: Returns the dimension of space of cycles in reduction.

- number\_of\_minimal\_nodes : Returns the number of minimal nodes.
- number\_of\_maximal\_nodes : Returns the number of maximal nodes.
- height: Returns the poset height the length of the longest chain.
- width: Returns the poset width the length of the longest antichain (subset, s.t. all elements are pairwise incomparable). The algorithm is based on Dilworth's theorem and it's proof via Kőnig's theorem: link
- minimum\_maximal\_chain : Returns the minimum size of maximal chains in the poset.
- avarage\_maximal\_chain : Returns the avarage size of maximal chains in the poset.

#### 2.2 Node Scores

- ancestors\_number: Returns the number of nodes higher than given
- ancestors\_height: Returns the size of maximum chain of subposet of nodes higher or equal than given
- ancestors\_width: Returns the size of maximum chain of subposet of nodes higher or equal than given
- ancestors\_cycles\_dimension: Returns the dimension of space of cycles in reduction of subposet of nodes higher or equal than given
- successors\_number: Returns the number of nodes higher than given
- successors\_height: Returns the size of maximum chain of subposet of nodes lower or equal than given
- successors\_width: Returns the size of maximum chain of subposet of nodes lower or equal than given
- successors\_cycles\_dimension: Returns the the dimension of space of cycles in reduction of subposet of nodes lower or equal than given

# 3 Experiments and Results

There are 360 experiments done. In the Figure 2 we can see how cases are distributed by size and dimension.

#### 3.1 Depth Poset Features

In the Figure 3 we can see the avarage poset scores values for each number of points n in the depth poset.

In the Figure 4 we can see the avarage mean node scores values in poset for each number of points n in the depth poset.

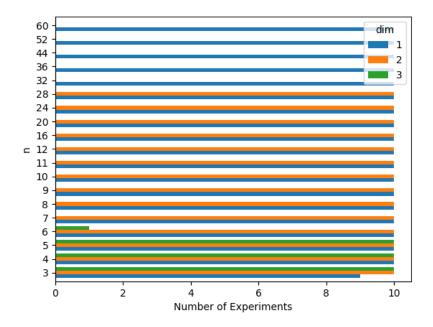

Figure 2: Size/dimension distribution of experiments

## 3.2 Column Reduction Poset Features

In the Figure 5 we can see the avarage poset scores values for each number of points n in the column reduction poset.

In the Figure 6 we can see the avarage mean node scores values in poset for each n in the column reduction poset.

#### 3.3 Row Reduction Poset Features

In the Figure 7 we can see the avarage poset scores values for each number of points n in the row reduction poset.

In the Figure 8 we can see the avarage mean node scores values in poset for each number of points n in the row reduction poset.

#### Depth Poset: Mean Poset Scores
